
τ = 0 applies NO protection: the release is an untilted mosaic of other people's haplotypes carrying zero target information. An attack that fails equally at τ = 0 and τ = 0.99 is therefore failing against the release FORM, not against the privacy mechanism. Standing constraint 7: a failed attack is a LOWER bound on distinguishability; only the proof gives an upper bound (figure 1).

⚠ RED: A4's τ = 0 value is EXACTLY 0.5 by construction (η = 0 makes every block statistic identically zero), so its z compares a multiplicity-inflated maximum against an exact value rather than two sampled ones. Shown rather than dropped. Its proper test is the corrected bound check: z = +2.65 against a critical value of 4.51.
