
The baseline is "guess the commonest 1000 Genomes allele at every site", which is PanMixer's own published comparator. Subset snp_only (258,610 sites), the paper's "SNPs overlapping with 1000 Genomes". ⚠ THEIR CURVE IS OUR DIGITIZATION OF THEIR FIGURE, NOT A PUBLISHED TABLE: the published paper prints no Beagle number at all (its Supplementary Fig. S4 is cited and absent), so the 49 points are read from the vector path of the PREPRINT's Fig. S2 and were independently re-extracted with a second tool (y agrees to 7e-05, x to 0.007% of the axis). ⚠ Our points are their CODE's protocol, which excludes nobody from the reference panel; their PAPER excludes the target individuals, and that run is still going.
